KEYS TO FLIES OF THE FAMILIES LONCHAEIDAE, SAPROMYZIDAE PALLOPTERIDAE, AND EASTERN UNITED STATES, WITH A LIST OF THE SPECIES OF THE DISTRICT OF COLUMBIA REGION.

By J. R. Malloch and W. L. McAtee,

Of the United States Biological Survey.

This paper contains a list of the species in the families Lonchaeidae, Pallopteridae, and Sapromyzidae that have been collected in the vicinity of the District of Columbia. To facilitate identification of the species so recorded, synopses of the genera and species are included which embrace all the species known to the authors which have been recorded from the territory east of the Mississippi River, and also all species likely to occur in that territory.

Many authors consider the families dealt with in this paper as subfamilies of Sapromyzidae, but there is very little real similarity between Sapromyzidae and Lonchaeidae. The Pallopteridae appear to be more closely related to the Lonchaeidae than to the Sapromyzidae, but there are some very important points of difference between this family and the other two which are emphasized in the discussion of the family characters.

All three families belong to the acalyptrate section of the Cyclorrhapha, having the abdominal spiracles in the membrane between the tergites and the sternites, close to the former. The auxiliary vein is present and complete, vibrissae are absent, and the basal cells of the wings are complete, the posterior one not prolonged at its apical posterior angle, characters which separate these families from most of their allies.

The very well developed frontal lunule of the Lonchaeidae which invades the anterior margin of the interfrontalia more or less triangularly and is generally setulose (fig. 2), the presence of a stigmatal and propleural bristle, very small size of preapical tibial bristle, and the complete, though apically indistinct, bisinuate sixth wing vein (fig. 4) separates the family from any other. No family which has the ovipositor very much elongated and sword-shaped, as has this one, has the propleura bare above the bristle and the from as described above. Other characters that may be mentioned are: Orbital bristle 1; and dorsocentrals, two pairs. The family is

more closely related to Ortalidae than to Sapromyzidae.

The Pallopteridae resemble the Lonchaeidae in having the ovipositor elongate sword-shaped, but the frons is transverse at its anterior margin as in Sapromyzidae, and the frontal lunule is concealed; the propleural bristle is absent or present; stigmatal bristle absent, or present but weak; sixth wing vein traceable to margin, straight; preapical dorsal tibial bristle absent; each orbit with one bristle as in Lonchaeidae; propleura bare.

The Sapromyzidae have no stigmatal bristle, and in this respect agree with many allied families, but the propleura are bare; the sixth wing vein is shorter than the seventh; the posterior basal cell of wing is very small and is not prolonged at apex; usually one or more pairs of the tibiae have a distinct preapical bristle, and both the mesopleura (except in Periscelis) and sternopleura have one or more strong bristles. Each orbit in American genera (except Periscelis) with two bristles; the frontal lunule is concealed; the anterior margin of frons transverse; postvertical bristles convergent or cruciate; propleural bristle present. The ovipositor is never sword-shaped.

Our only representative of the Pallopteridae occurs in humid, wellshaded localities; the Sapromyzidae, on the other hand, are rather inclinded to sit in the sun and they are sometimes attracted to flowers. The immature stages of these familes are practically unknown. larvae of a number of Lonchaeidae are known, however, and they live in sappy places under bark or in decaying vegetation where they are predaceous; the adults are of more random occurrence than those of the other familes here treated but agree with them in being attracted to light.

The number of species in the present list compared to that of the New Jersey State List of Insects 1 is:

Family.	New Jersey.	District of Columbia.
Lonchaeidae Pallopteridae Sapromyzidae	$\begin{array}{c}2\\1\\22\end{array}$	10 1 49

Of the 60 species here listed, 19 (indicated in text by asterisks) were originally described from material derived wholly or in part from our region. Thirty-two of the species have been collected on Plummer Island, Md., headquarters of the Washington Biologists' Field Club, and 17 others in adjacent parts of the Potomac River

¹ Ann. Rep. State Mus., (1909) 1910, Diptera by C. W. Johnson.

Valley. These facts of occurrence when not expressed in the detailed records are indicated by the abbreviations P. I. and V. P. I. respectively.

Previously described species, not yet collected, that should be obtainable in our region are: Steganolauxania latipennis Coquillett, New Jersey to Florida; Lauxaniella opaca Loew, New Jersey to Florida; and Sapromyza resinosa Wiedemann, New York to Florida.

Family LONCHAEIDAE.

Only one genus of this family has hitherto been recognized in North America, but there is every reason to believe that the group *Earomyia* Zetterstedt is entitled to at least subgeneric rank. Three of the species (aberrans, aterrina, and nigrociliata) included in this paper belong to *Earomyia*, having the frontal lunule bare, but they are included in the key to species of *Lonchaea* to facilitate identification and establish relationships.

The genotype of *Lonchaea* is *vaginalis* Fabricius, which has been stated by some European authors to be synonymous with *chorea* Fallén.

The genotype of *Earomyia* is *lonchaeoides* Zetterstedt, which for some obscure reason was renamed *frontata* by Becker in 1895.

The following key includes all species known to the authors to occur in North America. Some other species which have been recorded, we have not seen and do not attempt to include.

Genus LONCHAEA Fallén.

KEY TO SPECIES.

1.	Frons in both sexes with large irregular pits or depressions; a strong bristle
	near anterior margin of cheek vibrissata Malloch.
	Frons impunctate or almost so, not pitted2
2.	Several bristly hairs surrounding the stigmatal bristle 3
	No hairs surrounding stigmatal bristle11
3.	Fringes of calyptrae black or fuscous 4
	Fringes of calyptrae white or yellow 9
4.	Third antennal segment much less than twice as long as its greatest width;
	frontal lunule bare; ovipositor abnormally wideaterrima Malloch.
	Third antennal segment over twice as long as wide; frontal lunule with
	some hairs5
5.	Eyes in both sexes distinctly hairy, in the male conspicuously so; second
	costal division very long; disk of scutellum hairy6
	Eyes bare or almost so7
6.	Pteropleura hairy in center; cheeks with dense short erect fine hairs.
	pleuriseta Malloch.
	Pteropleura bare; cheeks with longer setulose hairsursina Malloch.
7	Tarsi entirely blackatritarsis Malloch.
	Tarsi largely yellowish 8
	45554—25—Proc.N,M.vol.65——25

8. Orbit with several long fine hairs above the bristle; cheeks, frons, and meso-

notum with rather dense erect black hairs; wings whitish or yellowish, infuscated at bases; scutellum with some long erect hairs on disk near apex as well as on the margins; pteropleura usually with one or two long hairs in center____hirta Malloch. Orbits bare or with a single hair above bristle; cheeks, frons, and mesonotum with more sparse black hairs; scutellum generally bare on disk; pteropleura bare____affinis Malloch. 9. Third antennal segment but little longer than wide; scutellum with four strong bristles and no fine hairs; face of male silvery; ovipositor of female nearly as broad as frons, acutely pointed at apex, the preapical hairs very short; auxiliary vein nearly fused with first at apex. arkansensis Malloch Third antennal segment about three times as long as wide; scutellum with some fine hairs on margins as well as the four long bristles; face of male not silvery; female ovipositor slender, very much narrower than frons. 10 10. Glossy upper portion of orbits black; orbital bristle not proximad of anterior ocellus; cheek with dense short stiff hairs; third antennal segment not over three times as long as wide, almost entirely orange red. ruficornis Malloch. Glossy upper portion of orbits blue; orbital bristle distinctly proximad of anterior ocellus; cheek with some short hairs and one or two longer bristles: third antennal segment over three times as long as its greatest width, upper half or more blackened; hind femur with several long bristles on apical half of anteroventral surface_____winnemanae Malloch. 11. Ovipositor of female nearly as wide as frons; calyptrae and their fringes white; tarsi largely yellowish; scutellum without fine hairs. Ovispositor slender, much narrower than frons; scutellum usually with fine hairs in addition to the strong bristles______ 12 12. Face and parafacials when viewed from above conspicuously whitish pruinescent; from of female dark steel-blue, shining, sparsely and evenly haired, and with a transverse depression midway between anterior margin and anterior ocellus; third antennal segment but little longer than wide; a strong curved bristle near anterior margin of cheek; tarsi slightly pale basally; calyptrae and their fringes brown; no fine hairs on scutellum. albiceps Malloch. Face but little whitish pruinescent when viewed from above; frons not steel-blue, and without a transverse depression; cheek either without a 13. Legs entirely black_____ At least the bases of tarsi yellowish________17 14. Fringes of calyptrae brown or fuscous______ 15 Fringes of calyptrae white; cheek without strong bristles_____ 16 15. Cheek with four outstanding bristles; no hairs between the scutellar bristles; frons slightly bluish or greenish; third antennal segment about 1.5 as long as wide______ quadrisetosa Malloch. Cheek without outstanding bristles; some fine hairs between the apical pair of scutellar bristles; from black_____angustitarsis Malloch. 16. Some fine hairs between the apical pair of scutellar bristles. vaginalis Fallen.

No fine hairs between the apical pair of scutellar bristles.

marylandica Malloch.

17.	Frontal lunule bare; fringes of calyptrae brown; interfrontalia with two
	series of incurved hairs on center; glossy portion of upper orbits micro-
	scopically strigose aberrans Malloch.
	Frontal lunule with setulose hairs at least on the sides except in nigro-
	ciliata; fringes of calyptrae whitish or yellowish except in nigrociliata
	and subpolita; glossy portion of upper orbits usually smooth (compare
	occidentalis and coloradensis) 18
18.	No minute hairs between the apical pair of scutellar bristles; third antennal
	segment not or barely over twice as long as its greatest width 19
	Some minute hairs between the apical pair of scutellar bristles; third
	antennal segment more than twice as long as its greatest width 20
19.	Tarsi brown; larger species, fully 4 mm, in length marylandica Malloch.
	Tarsi pale vellow: smaller species, less than 4 mm, in length.
	laticornis Meigen.
20.	Fringes of calyptrae fuscous21
	Fringes of calyptrae white or yellow; thorax and abdomen bluish 22
21.	Frontal lunule bare; head and thorax black, abdomen slightly bluish,
	nigrociliata Malloch.
	Frontal lunule hairy; thorax and abdomen blackish blue_subpolita Malloch.
22.	Width of male frons at anterior margin equal to at least half the entire
	length of frons; preapical dorsal pair of hairs on ovipositor very long;
	hairs at angle of calyptrae much longer than rest of fringe; upper
	orbits largely microscopically strigose occidentalis Malloch.
	Width of male frons at anterior margin not nearly equal to half its entire
	length; preapical dorsal hairs on ovipositor very short; fringes of
	calyptrae of uniform length 23
23.	Third antennal segment about twice as long as wide; upper frontal orbits
	granulose coloradensis Malloch.
	Third antennal segment at least three times as long as wide; upper frontal
	orbits largely or entirely polished24
24.	Only the basal segment of each tarsus yellow longicornis Williston.
	Basal two or three segments of each tarsus yellow25
25.	Larger species, over 4 mm. in length; hypopygium as in Figure 3,
	nudifemorata Malloch.
	Smaller species, less than 4 mm. in length; hypopygium of male as in
	Figure 1 polita Say.
	posterior poster

- L. aberrans Malloch.—Mount Vernon, Virginia, April 19, 1917, McAtee.
- * L. albiceps Malloch.—Washington, District of Columbia, May 29, 1912, McAtee.
- L. laticornis Meigen.—Common and widely distributed; dates of collection range from May 8 to October 3; comes to light. P. I.
- *L. marylandica Malloch.—Plummer Island, Maryland, bred April 24, 1915, from larva collected under bark, April 7, H. S. Barber.
- * L. nudifemorata Malloch.—Plummer Island, Maryland, April 21, 1912, McAtee; Falls Church, Virginia, May 10, N. Banks.
- L. polita Say.—The most numerous species; the season for active imagines runs from March 29 to October 29; the species has been

subarcuata Johnson

bred from old pumpkin vines, cabbage stalks, and butternut hulls; comes to light. P. I.

L. ruficornis Malloch.—Washington, District of Columbia, May 29, 1914, L. O. Jackson.

* L. quadrisetosa Malloch.—Plummer Island, Maryland, August 11, 1912, McAtee; June 3, 1914, R. C. Shannon; District of Columbia. D. W. Coquillett.

L. vibrissata Malloch.—Cupid's Bower Island, Maryland, July 8, 1915, R. C. Shannon; Stubblefield Fall, Virginia, October 23, 1921. Malloch; Falls Church, Virginia, May 10, N. Banks; Mount Ver-

non, Virginia, July 4, 1917, at honey dew, McAtee.

prescutellar pair of acostichals absent

*L. winnemanae Malloch.—Cupid's Bower Island, Maryland. July 8, 1915; Dead Run, Virginia, April 11, 1915, R. C. Shannon: Virginia near Plummer Island, April 18, 1909, McAtee; Falls Church, Virginia, June 6, August 25, N. Banks; College Park. Maryland, May 25, 1913, F. Knab.

Family PALLOPTERIDAE.

This family is represented by but one genus in North America, a key to the species of which follows:

Genus PALLOPTERA Fallén.

KEY TO SPECIES.

1. Thorax with one or two pairs of dorsocentral bristles, the anterior one when

present weak; propleural bristle absent; stigmatal bristle weak or absent;

	presentenar pair of acostenars absent subarcuata Johnson.
	Thorax with four pairs of dorsocentrals, the anterior pair sometimes
	weak
<u>·)</u> .	Mesopleura bare3
	Mesopleura setulose8
3.	Both cross-veins of wings unclouded4
	At least the outer cross-vein of wings distinctly clouded6
4.	Humeri entirely gray, concolorous with disk of thorax
	claripennis Malloch, new species.
	Humeri yellow, contrasting with the gray disk of thorax5
5.	Thorax with about four series of weak whitish hairs between the anterior
	pair of dorsocentrals; stigmatal bristle absent terminalis Loew.
	Thorax with about eight series of short black setulose hairs between the
	anterior pair of dorsocentrals; stigmatal bristle present but weak
	ustulata Meigen.
6.	Thorax gray, densely pruinescent, humeri yellow; wing with the costal cell
	almost entirely infuscated, and an infuscation at apex
	subusta Malloch, new species.
	Thorax yellowish; wing with the entire costal region broadly infus-
	cated 7
7.	Propleural and stigmatal bristles both absent; head thorax, and abdomen
	grayish pruinescentsetosa Melander.
	Propleural bristle present; stigmatal bristle absent; thorax and abdomen
	not gray pruinescent albertensis Johnson.

S. Abdomen without distinct black markings on tergites_______9

Abdomen with either round spots or black vittae on apices of tergites_______10

Costa brown from near base to apex______ jucunda Loew.
 Costal cell and a space beyond apex of first vein hyaline___ arcuata Fallen.

10. Abdominal tergites with conspicuous black spots near apices from which the bristles arise; propleural bristles absent______ superba Loew.

Abdominal tergites with the posterior margins narrowly and the sides broadly black; propleural bristle present_____ similis Johnson.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

P. superba Loew.—A handsome fly which is fairly numerous in damp shady localities of the Piedmont region; it has been collected from June 8 to October 28; and is known to come to light. P. I.

DESCRIPTIONS OF TWO WESTERN SPECIES.

The two following new species have the head, scutellum, abdomen and legs yellowish testaceous, and the thorax black with dense gray pruinescence. In *claripennis* the humeri are also gray, while in *subusta* they are yellowish testaceous.

PALLOPTERA CLARIPENNIS Malloch, new species.

Male.—Distinguished from all other species of the genus by the entirely clear wings. Structurally similar to ustulata.

Length, 3.25 mm.

Type.—Palo Alto, California, August 3, 1895, Lot. 84, (Type Cat. No. 26387, U.S.N.M.)

PALLOPTERA SUBUSTA Malloch, new species.

Male.—Differs from usta Meigen in having the fuscous markings of wings smaller, the one at apex of wing being much less distinct, that on outer cross-vein not extending behind fifth vein, and the infuscation in subcostal cell not extending beyond the veins bounding the cell. The abdomen is pale yellowish testaceous, not black.

Length, 4-5 mm.

Type and one paratype.—Palo Alto, California, August 3, 1895; one paratype, Stanford University, California, September 30, 1901. (Type Cat. No. 26388, U.S.N.M.)

Family SAPROMYZIDAE.

KEY TO GENERA.

1. Basal antennal segment elongated, as long as or almost as long as the elongated second segment, with some minute setulose hairs at apex below; third segment much more than four times as long as wide, appearing cylindrical; face convex___________2

Basal antennal segment short, not as long as second, bare at apex below____4

2.	Sternopleurum with two strong bristles; arista with very dense short hairs
	above and belowLauxania Latreille.
0	Sternopleurum with only one strong bristle; arista long haired above 3
0.	Marginal cell of wing very much narrower than submarginal, equally wide
	on its entire length Steganolauxania Frey.
	Marginal cell at its widest part as wide as submarginal, much narrowed
4	from apex of first vein basadLauxaniella Malloch.
4.	Anterior orbital bristle absent
F.	Anterior orbital bristle present 5 Anterior orbital bristle directed inward 6
e,	
G	Anterior orbital bristle directed backward8 Ocellar bristles minute; face much swollen, projecting very much beyond
0.	eyes in profile; anterior pair of orbital bristles small, closer together than
	the upper pair, and situated very distinctly nearer to bases of antennae
	than to upper pair Physogenia Macquart.
	Ocellar bristles long and strong; face not or but little projecting; anterior
	orbital bristles large
7.	Anterior orbital bristles strong, situated about midway between bases of
•	antennae and upper pair and in line with them; face glossy, with a dis-
	tinct rounded central convexity; third antennal segment slender, longer
	than height of head Pachycerina Macquart.
	Anterior pair of orbital bristles moderately strong, situated very close to
	upper pair; face not glossy, with a very slight longitudinal convexity or
	almost flat; third antennal segment tapered, not as long as height of head,
	Camptoprosopella Hendel.
8.	Either second or third wing-vein with setulose hairs basally9
	Second and third wing-veins bare11
9.	Setulae present on base of second vein before furcation of third,
	Xenochaetina Malloch.
	Setulae present on base of third vein distad of furcation from second 10
10.	Fore femur with a comb of short black setulae on apical third of antero-
	ventral surface; pteropleura with some fine black hairs in center,
	Eusapromyza Malloch (European).
	Fore femur without a comb of setulae as above; pteropleura bare,
	Peplomyza Haliday (European).
11.	Presutural bristle absent; head longer than high, face much receding below;
	orbits rather densely covered with minute black hairs at bases of antennae,
	Trigonometopus Macquart.
	Presutural bristle present; head higher than long, the face not much re-
	ceding below, and the orbits not noticeably haired at bases of an-
10	tennae
L = .	
12	Sternopleurum with two strong bristles, the anterior one the weaker 14 Frons broader than long, concave in center anteriorly; ocellar bristles
	minute; thorax with three pairs of dorsocentrals and one pair of pres-
	cutellar acrostichals Neogriphoneura Malloch.
	Frons sometimes longer than broad, not concave in center anteriorly; thorax
	with two pairs of dorsocentrals Deceia Malloch.
14	Face decidedly and evenly convex, glossy Caliope Haliday.
	Face flat or not evenly convex, opague or subopaque15
15.	Intra-alar bristle present; the small black costal setulae on wing continued
	beyond apex of second vein but not extending to apex of third,
	Minettia Robineau-Desvoidy.
	Intra-alar bristle absent16

16. Scutellum convex above, much broader than long; second wing-vein undulated; face with a slight transverse ridge near mouth-margin; wing fuscous, with small clear spots_______Trypetisoma Malloch.

Scutellum more or less flattened above; second wing-vein not undulated: face without a transverse ridge; wings not marked as above_______17.

17. The small black setulae continued beyond apex of second vein but not continued to apex of third_________Sapromyza Fallen.

The small black costal setulae continued to apex of third vein where they abruptly cease____________Sapromyzosoma Malloch.

Genus LAUXANIA Latreille.

KEY TO SPECIES.

Knobs of halteres, bases of wings, and fore legs except the bases of tibiae black; dorsocentrals 3______ cylindricornis Fabricius. Knobs of halteres, bases of wings, and a part of fore legs yellowish____ 2
 Dorsocentrals 3; fore tibiae black______ nigrimanus Coquillett. Dorsocentrals 4; fore tibiae yellow______ albiseta Coquillett.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

L. cylindricornis Fabricius.—Fairly numerous in Piedmont localities; has been collected from April 16 to June 29. P. I.

Genus STEGANOLAUXANIA Frey.

This genus is represented in our general region by one species, latipennis Coquillett. The genus was erected by Frey in 1918 and is closely related to Steganopsis de Meijere described from the Dutch East Indies.

Genus LAUXANIELLA Malloch.

Generic characters.—Differs from Lauxania in having only one sternopleural bristle. In the structure of the antennae it is similar to that genus and differs from other genera.

Genotype.—Lauxania femoralis Loew.

KEY TO SPECIES.

² Sapromyzosoma citreifrons male has the costal setulae very weak near the apex of third vein, but the marked wings, yellow color, and other characters associate it more definitely with this genus than with Sapromyza. The female is typical of this genus.

yellowish; scutellum largely velvety black_____ femoralis (Loew).

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

L. femoralis Loew.—Spring Hill, Virginia, August 26, 1922, H. L. Viereck; Falls Church, Virginia, June 26, July 5, August 24, September 17; High Island, Maryand, July 8, N. Banks; Glen Echo, Maryland, August 3, 6, 1922, L. L. Buchanan; July 30, August 2, 1922, Malloch.

L. trivittata Loew.—Has been collected several times in the Piedmont area, at dates ranging from June 14 to August 22; taken twice on flowers of Ceanothus americanus. P. I.

Genus PHYSOGENIA Macquart.

We have seen but one species from America, vittata Macquart, represented in material from Cuba, Brazil, and Nicaragua.

Genus PACHYCERINA Macquart.

We have seen only one species of this genus from America, represented by specimens from Florida and Nicaragua. These were named flavida Wiedemann, by Coquillett, and probably are the same species as ornata Melander, described from Mexico, synonymy we venture even though Wiedemann's description of the thoracic coloration does not agree exactly with that of the specimens above referred to.

Genus CAMPTOPROSOPELLA Hendel.

Two species of this genus occur in our region which may be separated by the characters cited below.

KEY TO SPECIES.

- - 2. Fore legs not darker than mid and hind pairs; arista loosely long plumose, vulgaris Fitch.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

C. verticalis Loew.—Much rarer than vulgaris; Woodridge, District of Columbia, August 22, 1915, J. Silver; Beltsville, Maryland, June 9, 1915, August 14, 1914, McAtee. Has been taken in Illinois in sandy regions along the Mississippi River and we have also seen it from Florida.

C. vulgaris Fitch.—The commonest species of the family in North America, occurring throughout our region in woodlands; extreme dates of collection; May 20 and October 12: comes to light; occasionally on flowers. P. I.

Genus XENOCHAETINA Malloch.

Generic characters.—Similar in general habitus to Caliope, but the base of the second wing-vein has one or two small setulae on upper side. The fore femur has a comb of minute setulae beyond middle on anteroventral surface as in many species of Sapromyzosoma.

Genotype.—Lauxania muscaria Loew.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

X. muscaria Loew.—Common in the Piedmont region; the season as at present known extends from May 14 to October 16. P. I.

Genus TRIGONOMETOPUS Macquart.

A key to the species of this genus appeared in 1923.3

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

T. vittatus Loew.—Stubblefield Fall, Virginia, October 23, 1921, Malloch.

Genus NEOGRIPHONEURA Malloch.

Generic characters.—Frons concave on anterior half in center, viewed from above the anterior margin has a rounded central emargination; ocellar bristles minute, very much smaller than the postvertical pair; anterior orbital bristles long and strong, directed slightly mesad and caudad; eyes tapered below; face slightly convex, the lower margin a little protuberant; mouth with a slight rim; arista plumose above, short haired on apical half below; sternopleu-

³ Proc. Ent. Soc. Wash., vol. 25, p. 48, 1923.

⁴⁵⁵⁵⁴⁻²⁵⁻Proc.N.M.vol.65-26

rum with one strong bristle; area of mesonotum between dorsocentral and supra-alar bristles bare; hypopygium small; costa as in *Minettia*. *Genotype*.—*Sapromyza sordida* Wiedemann.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

N. sordida Wiedemann.—Dead Run, Virginia, August 3, 1915, V. A. Roberts. This species is represented also in material examined by us from Sebastian and Paradise Key, Florida, and Knoxville, Tennessee. It was originally described from the West Indies, and has been recorded from Porto Rico, St. Vincent, and Georgia in addition to the above. It is represented in the United States National Museum collection by specimens from Lake Worth, Florida, Texas, and Nicaragua.

Genus DECEIA Malloch.

Generic characters.—Differs from Minettia in having one sternopleural bristle, and two pairs of dorsocentrals, and the intra-alar absent. All tibiae with a preapical dorsal bristle. From Lauraniella it differs in having the basal antennal segment very much shorter than the second and bare at apex below, and third not four times as long as its greatest width except in incongrua.

This genus is divisible into four subgenera, as indicated in the key given below. The genus contains some species which appear to be related to other genera about as closely as they are to the typical species and in the future when material from other faunal regions is carefully studied it may be necessary to recognize as valid genera the groups now accepted as subgenera.

KEY TO SUBGENERA.

- 2. Frons longer than wide, flat in profile and opaque; face subopaque; eyes distinctly narrowed below________ Neodeceia Malloch.

 Frons either not longer than wide or the face is distinctly glossy______ 3
- 3. Eyes distinctly narrowed below; frons more or less shining, but not uniformly so; face glossy, distinctly convex______ Melanomyza Malloch.

 Eyes not narrowed below; frons uniformly subopaque; face almost flat, slightly shining______ Trivialia Malloch.

Subgenus NEODECIA Malloch.

This subgenus is represented by but one species in the fauna of the United States. It does not occur within our region, being confined to Florida and Cuba so far as known.

Type of the subgenus.—Lauxania cineracea Coquillett.

Subgenus TRIVIALIA Malloch.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

* Deceia (Trivialia) fuscocapitata Malloch.—This species has been taken only once, in Virginia near Plummer Island, July 4, 1915, McAtee.

Subgenus DECEIA Malloch.

Type of the subgenus.—Sapromyza erevecoeuri Coquillett.

KEY TO THE SPECIES.

1. Ocellar bristles parallel, at least as long as anterior orbitals and much longer than postvertical pair; the longest hairs on upper side of arista shorter than third antennal segment; palpi fuscous; fore tarsi whitish yellow_____ crevecoeuri Coquillett.

Ocellar bristles divergent, much shorter than the anterior orbitals and equal to postvertical pair; longest hairs on upper side of arista as long as third antennal segment; palpi yellow; fore tarsi whitish, apical segment in male black, in female brownish______ wetmorei Malloch.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

D. crevecoeuri Coquillett.—Has been taken a number of times on Plummer Island, Maryland, from June 30 to August 6 (once at light); and at Glen Echo, Maryland, June 25 to August 22.

Subgenus MELANOMYZA Malloch.

Type of the subgenus.—Laurania gracilipes Loew.

KEY TO SPECIES.

 Frons without velvety black markings; hairs on upper side of arista barely longer than those on under side; antennae extending slightly beyond mouth-margin, third segment at least four times as long as wide; scutellum without velvety black margin______incongrua Malloch.

Frons with velvety black markings; hairs on upper side of arista much longer than those on under side; antennae not extending to mouth-margin, third segment not three times as long as wide; scutellum more or less broadly velvety black on posterior margin.

broadly velvety black on posterior margin_______2

2. Frons with a large subquadrate velvety black spot in center anteriorly;
ocellar triangle very short, not extending to middle of frons,

gracilipes Loew.

Frons with a wedge-shaped black mark on each side of interfrontalia anteriorly, frontal triangle extending to anterior margin of frons, rather broad anteriorly; orbits almost glossy, the shining stripe not interrupted between the bristles; scutellum velvety black only on margin,

intermedia Malloch.
Frons largely velvety black anteriorly but more conspicuously so on the same areas as intermedia, the frons not so distinctly shining on orbits, the latter shining only on two small spots surrounding bases of the bristles, scutellata Malloch.

D. gracilipes Loew.—Common; has been collected from June 19 to September 17; in copula August 6; comes to light. P. I.

*D. intermedia Malloch.—Common; the known season extends

from June 11 to September 12; is attracted to light. P. I.

*D. scutellata Malloch.—Common; dates of collection range from May 30 to August 29; obtained thus far only in Piedmont localities. P. I.

Genus CALIOPE Haliday.

We have retained in this genus two species which appear to be closely related to the genotype, but as the latter is not available to us we can not say definitely whether they really belong to the genus or not. The two species may be separated by means of the synopsis below.

KEY TO SPECIES.

LIST OF SPECIES OF THE DISTRICT OF COLUMBIA REGION.

*C. flaviceps Loew.—Rosslyn, Virginia, April 23, 1913, R. C. Shannon.

Genus MINETTIA Robineau-Desvoidy.

KEY TO SPECIES.

- 1. Knobs of halteres black; prosternum bare; thorax and abdomen black 2

 Knobs of halteres yellow; prosternum usually with a few hairs 4
- 2. All tarsi yellowish; male hypopygial forceps slender, heavily chitinized and glossy on their apical halves; face with two small rounded humps near nouth margin_______longipennis Fallen.

Only mid and hind tarsi yellowish, the fore pair blackened; hypopygial forceps of male stout; face without two small humps as above____ 3

3. Thorax with four pairs of dorsocentral bristles; usually four series of setulae between the dorsocentrals; male hypopygium as in figures 5, 6, 7.

americana Malloch.

Thorax with three pairs of dorsocentrals; six series of setulae between the dorsocentrals; male hypopygium as in figure 8_____ obscura Loew.

4. Thorax and scutellum black, densely pale gray pruinescent, the margin of scutellum sooty black; abdomen yellowish testaceous; not annulated, fore and mid femora and fore tibiae partly blackened male hypopygium as in figure 9_______lupulina Fabricius.

Thorax and scutellum not as above; if gray pruinescent the scutellum

Thorax and scutellum not as above; if gray pruinescent the scutellum has no sooty black margin_______5

⁴ This species has been recorded from North America, but erroneously. The records without doubt refer to one or other of the next two species in key.

5.	Face pale shining testaceous, with a round shining brown or blackish spot
	on each side at middle; frons and parafacials concolorous with face, the
	former with three elongate black stripes, the latter with two round black-
	ish spots, one at base of antenna and the other below eye,
	eucephala Loew.
	Face not as above, unspotted, with a single central velvety black spot,
	or if with two blackish spots the entire head is densely gray prui-
	nescent and the other markings are not as above6
6.	Face without a central velvety black spot 7
	Face with a central velvety black spot
-	Thorax largely or entirely blackish and densely gray pruinescent; hind
٠.	
	tibia with a fuscous band near base and another at apex8
	Thorax and abdomen yellowish testaceous, shining; hind tibia unicolorous
	yellowish, not annulate 11
S.	Palpi black; large species, about 5 mm. in length; abdomen gray pruines-
	cent, the apical two segments each with a narrow fuscous fascia, scutel-
	lum not subtruncate at apex buchanani Malloch, new species.
	Palpi yellow; species in other respects not as above9
0	Large species, 5-6 mm. in length; each adbominal tergite with a fuscous
θ.	
	fascia anteriorly magna Coquillett.
	Smaller species, averaging less than 4 mm. in length; abdominal tergites
	without complete fasciae10
10.	Each abdominal tergite with a brownish black transverse spot on each side;
	abdomen yellowish glauca Coquillett.
	Abdomen yellowish testaceous and without lateral spotscana Melander.
11.	One of the setulae near upper extremity of the series on side of face strik-
	ingly longer and stronger than the others; arista almost bare,
	ordinaria Melander.
	All the lateral facial hairs small and weak; arista plumose or short-
10	
14.	Arista plumose; dorsum of thorax immaculate or with a more or less
	distinct grayish or fuscous median stripe; ocellar bristles longer than
	postvertical pair; second abdominal tergite of female with several long
	bristles on each side of posterior margin; abdomen unspotted but
	sometimes indistinctly fasciate13
	Arista short-haired, small species, not over 3 mm. in length; dorsum of
	thorax with a small brown spot at base of each bristle and hair; ocellar
	bristles very small; abdomen with a blackish central spot on each tergite
	except the first, and a smaller spot on each side of the apical two or three
	tergitespunctifer Malloch.
13.	Wings distinctly infuscated fumipennis Melander.
	Wings yellowish14
14.	Thorax immaculate flaveola Coquillett.
	Thorax with a grayish or fuscous central stripe,
	flaveola, var. univittata Coquillett.
15	Scutellum with a black mark on each side; base of antennae black 16
10.	Scutellum and antennae entirely yellow
10	
16.	Pleura immaculateoctopunctata Wiedemann.
	Pleurae with one or two black spots_ octopunctata, var. slossonae Coquillett.
17.	. Thorax quadrivittate; abdomen with conspicuous brown spots,
	valida Walker.
	Thorax and abdomen testaceous, immaculate puncticeps Coquillett.

*M. americana Malloch.—Common; has been collected from April 24 to June 22. P. I.

* MINETTIA BUCHANANI Malloch, new species.

Male.—Similar in color to magna, but the palpi are black, and the abdomen is densely gray pruinescent with a narrow fuscous fascia on middle of third and another on fourth tergites. The general habitus is similar to that of magna, but the arista has the hairs shorter than width of third antennal segment, the scutellum is not subtruncate apically between the bristles, there are more outstanding setulae in center of mesopleura which extend to below the bristle, and the size is smaller.

Length, nearly 5 mm.

Type.—Beltsville, Maryland, May 21, 1922, swept from herbage in woodland (J. R. Malloch). Cat. No. 26389 U. S. N. M.

*M. glauca Coquillett.—Great Falls, Virginia, May 19, 1915, Mc-Atee; Virginia near Plummer Island, May 20, 1914, R. C. Shannon; Maryland near Plummer Island, June 5, 1903, W. V. Warner; Beltsville, Maryland, May 2, 1915, on flowers of Aronia arbutifolia Mc-Atee; Marlboro, Maryland, May 13, H. S. Barber.

M. lupulina Fabricius.—Very common; the extreme dates of collection are May 14 and October 5; has been taken on flowers of Ceanothus americanus, and Tephrosia virginica. P. I.

*M. magna Coquillett.—This, the largest local species of the family, is fairly common; it has been collected from May 31 to September 17. V. P. I.

M. obscura Loew.—Very common; the season as at present known runs from April 25 to June 29; comes to light; and has been collected on the flowers of Aruncus aruncus. P. I.

M. ordinaria Melander.—Plummer Island, Maryland, August 26. 1902, E. A. Schwarz and H. S. Barber; Chain Bridge, Virginia. September 18, 1921, Malloch; Washington, District of Columbia. August 13, N. Banks.

M. puncticeps Coquillett.—Plummer Island, Maryland, May 25, 1902, H. S. Barber; May 23, 1914, June 8, 1914, at light, R. C. Shannon; June 15, 1905. D. H. Clemons.

M. valida Walker.—Has been collected several times at dates ranging from May 1 to October 14; comes to light. P. I.

Genus SAPROMYZA Fallén.

KEY TO SPECIES.

 Wings black, with numerous small clear spots, the most conspicuous one at apex; head, thorax and apical abdominal segment with numerous small

brown spots and dots, the greater part of abdomen dark brown, with pale gray pruinose spots at bases of bristles and setulae; thorax with four pairs of dorsocentrals and four or five pairs of strong acrostichals, stictica Loew. Wings clear, or at least without small clear spots on a dark ground____ 2 2. Wings with the anterior, or costal, half, and the cross-veins browned: thorax quadrivittate with brown, and with three pairs of dorsocentrals and only one, prescutellar, pair of strong acrostichals; second costal division less than half as long as first; one genal hair much longer and stronger than the others_____ umbrosa Loew. Wings entirely hyaline; thorax with one pair of acrostichals______ 3 3. From wholly glossy black, sometimes yellowish on anterior margin; thorax and abdomen wholly black, shining, the former with four pairs of dorsocentrals; face glossy black in center; second costal division a little less than half as long as first______4 Frons not wholly glossy black, usually some part of it yellowish and except in the entirely yellow species with distinct pruinescence; if largely or entirely shining black, there are only three pairs of dorsocentrals; thorax with two to four pairs of dorsocentrals_____ 5 4. Face and from highly glossy, without pruinescence; third antennal segment at least four times as long as wide, not tapered to apex; longest hairs on arista decidedly longer than its basal diameter; acrostichals between dorsocentrals in two series_____ quadrisetosa Thomson, variety. Face with distinct gray pruinescence below antennae; third antennal segment not over 2.5 times as long as broad, tapered apically; longest hairs on arista not longer than its basal diameter; acrostichals between dorsocentrals in four series____ nigerrima Melander (=blaisdelli Cresson). Face with distinct gray pruinescence below antennae; third antennal segment at least three times as long as broad, tapered apically; longest hairs on arista longer than its basal diameter; acrostichals between dorsocentrals in four series__ quadrisetosa Thomson (=vanduzeei Cresson?). 5. Thorax with four pairs of dorsocentrals and distinct brown vittae; abdomen with brown dorsal spots; second costal division much shorter than half as long as first_____6 Thorax with two or three pairs of dorsocentrals; second costal division almost or quite half as long as first______ 10 Thorax with four pairs of dorsocentrals, and without vittae; abdomen largely fuscous, without dorsal spots; second costal division fully half as long as first; legs entirely yellow; a large portion of third antennal segment and the palpi fuscous_____ fusciventris Malloch. 6. Fore femur without a comblike series of minute setulae between middle and apex on anteroventral surface; bristles on posterior margins of dorsal abdominal segments not set in black or brown spots; no dark spot in front of mesonotal suture laterad of the outer vitta_____ Fore femur with a comblike series of minute setulae between middle and apex on anteroventral surface; bristles on posterior margins of dorsal abdominal segments set in black or brown spots; a brown or

vitta_____

fuscous spot in front of suture on mesonotum laterad of the outer

⁵ See p. 25. This is now placed in a new genus but because of similarity to species of Sapromyza is included in the above key.

18	PROCEEDINGS OF THE NATIONAL MUSEUM. Vol. 65
7	Apices of tibiae pale; superior forceps of male hypopygium long, but not
٠.	very slender, their inner margins on apical third minutely serrate, inferior
	pair cleft at apices, the arms of dissimilar lengths; fifth sternite with
	two slender chitinized processes on posterior margin which are directed
	backward (figs. 10, 10a); no dark spot in middle of mesopleurum.
	serrata Malloch.
	Apices of tibiae blackened; superior forceps of male hypopygium not ser-
	rated on inner margins apically; usually a distinct brown spot in middle
	of mesopleurum8
6.	Superior forceps of male hypopygium short and stout, inferior pair with
	the apical branches of almost equal size; fifth sternite of male with two
	slender backwardly directed processes on posterior margin (figs. 11, 12).
	obtusilamellata Malloch.
	Superior forceps of male hypopygium long and slender, branches of inferior
	pair unequal in size (figs. 15, 15a); fifth sternite of male without processes
	on posterior margin quadrilineata Loew.
9.	Superior forceps of male hypopygium long and slender, inferior pair long
	and slender, much curved, with a short tooth beyond middle (fig. 13);
	larger species, 4 mm. in length, color pale, the spots on abdomen sometimes
	but little darker than remainder of segment; central pale stripe on
	mesonotum distinctly narrowed at anterior extremity_ annulata Melander.
	Superior forceps of male hypopygium short and stout, their apical margins
	concave (figs. 14, 14a); small species, 3 mm. in length; color darker, the
	spots on abdomen always fuscous and much darker than remainder of
	segment; central pale stripe on mesonotum not distinctly narrowed at
	anterior extremity pictiventris Malloch.
10.	Thorax with two pairs of dorsocentrals; shining yellow species with a
	round shining black spot on each side of the apical two or three abdomi-
	nal tergites rotundicornis Loew.
	Thorax with three pairs of dorsocentrals, abdomen not as above 11
11.	Yellow species; from glossy, with a black spot in middle; apical half of
	third antennal segment black (Wyoming, Moutana) cyclops Melander.
	Yellow species; from shining unicolorous yellow; third antennal segment
	slightly infuscated above on apical half monticola Melander.
	Black species from largely, antennae entirely, blackish12
12.	Face with a round black or brown spot on each side in center; densely pale
	gray pruinescent species; thorax vittate; tibia with a pale band at base
	and another beyond middlevittigera Coquillett.
	Face immaculate; moderately pruinose species, with the thorax not vittate
	and tibia not banded13
13.	Face and from highly polished, only the facial orbits gray pruinescent; face
	slightly bulbous in center just below antennae; third antennal segment at
	least three times as long as wide; arista short haired; acrostichals in
	four irregular serieselisae Meigen.
	At least the face gray pruinescent, not bulbous; third antennal segment
	about twice as long as wide14
14.	Frons opaque, indistinctly reddish on anterior margin; thorax opaque, with
	rather dense brownish pruinescence, the acrostichals in two series; arista
	nearly bare brachysoma Coquillett.
	Evens chining consciolly on orbits conspicually undich test cons

From shining, especially on orbits, conspicously reddish testaceous on anterior margin; thorax shining, faintly gray pruinescent, the acrostichals

in four series between anterior dorsocentrals; arista pubescent, hyalinata Meigen (=nigrans Melander).

S. annulata Melander.—Fairly common in Piedmont areas; has been taken at Difficult Run, Virginia, September 14, 1913, R. C. Shannon; on Plummer Island, Maryland, June 8, 1914, at light, June 14, 1913, and July 31, 1913, R. C. Shannon; May 30, 1907, and June 7, 1914, McAtee, August 3, 1915, at light, V. A. Roberts; at Glen Echo, Maryland, at six dates extending from July 10 to August 28, Malloch; Maywood, Virginia, May 21, 1922, McAtee; and Beltsville, Maryland, May 21, 1922, Malloch.

S. brachysoma Coquillett.—Stubblefield Fall, Virginia, October 23, 1921, Malloch; Dead Run, Virginia, March 13, 28, 1915, March 12, 1916, March 13, 1922; April 4, 1915; and Maryland near Plummer

Island April 5, 1914, R. C. Shannon.

*S. obtusilamellata Malloch.—Glen Echo, Maryland, July 17, 23, 1921, June 11, 1922; Cabin John, Maryland, July 31, 1921, Malloch.

* S. pictiventris Malloch.—Fairly common; the season as at present known extends from April 23 to August 24. P. I.

S. quadrilineata Loew.—Very common; extreme dates of collection are April 24 and September 23; comes rather frequently to light. P. I.

* S. serrata Malloch.—District of Columbia, D. W. Coquillett: Rock Creek, District of Columbia, June 15, 1913, R. C. Shannon; Glen Echo, Maryland, June 1, 18, 25, July 2, 9, 1922, Malloch.

*S. umbrosa Loew.—Plummer Island, Maryland, June 8, 1914, at light, E. A. Schwarz and R. C. Shannon; Glen Echo, Maryland, June 25, July 2, 1922, Malloch; Beltsville, Maryland, June 23, 1918, July 4, 1915, McAtee; June 25, 1915, R. C. Shannon; May 21, 1922, Malloch; Odenton, Maryland, June 20, 1915, June 11, 1922, McAtee.

S. vittigera Coquillett.—Stubblefield Fall, Virginia, October 23, 1921; Glen Echo, Maryland, June 11, 1922, Malloch.

Genus SAPROMYZOSOMA Malloch.

KEY TO SPECIES.

1.	. Wings with at least both cross-veins and the apices of second, third
	and fourth veins distinctly infuscated
	Wings with at most the cross-veins distinctly infuscated 10
2.	Third vein with two fuscous spots in addition to the one at inner cross
	vein and the one at apex
	Third vein with only one fuscous spot in addition to the one at inner
	cross-vein and the one at apex

3.	Hind femur of male with many black setulae ventrally; thorax with three pairs of dorsocentral bristles; arista long haired; hind femur without
	preapical anteroventral bristle notata Fallen [European only].
	Hind femur of male without black setulae ventrally; arista short haired_ 4
4.	Hind femur without an anteroventral bristle near apex; thorax with four
	pairs of dorsocentrals occidentalis Malloch.
	Hind femur without an anteroventral bristle near apex; thorax with three
	pairs of dorsocentrals; arista very short haired,
	deceptor Malloch, new species.
	Hind femur with a rather strong outstanding anteroventral bristle near
_	apex; thorax with three pairs of dorsocentrals5
5.	Eighth abdominal tergite with a backwardly directed spine at apex of the
	downwardly directed lateral extension on its posterior angle; hypopygium
	as Figures 18, 20, and 21
	at apex of the lateral process on its anterior angle; hypopygium as la
	Figures 24 and 26 pernotata Malloch.
6	Second, and sometimes part of basal or third segment of hind tarsus black-
0.	ened, in male the blackened parts generally dilated
	Hind tarsi pale, the segments in male not dilated11
7.	Two segments of hind tarsus in male and female partly blackened; in males
	with a pair of long, apically dilated hairs at apex of the three basal seg-
	ments 8
	Only one segment of hind tarsus blackened; no such hairs on tarsus of
	males9
8.	Second and third segments of hind tarsus in both sexes partly blackened,
	in male broadly dilated; almost all of marginal and submarginal cells of
	wings blackenedornatipes Johnson.
	Apices of basal and second segments of hind tarsus in both sexes blackened,
	the second in male broadly dilated; fuscous mark on costal margin of
	wings sometimes broadly interrupted along costa between cross-veins and again, narrowly, between apices of second and third veins,
	melanderi Johnson.
9	Costal margin of wing suffused from apex of auxiliary vein to apex of
٠.	fourth, less distinctly so between cross-veins; second segment of hind
	tarsus distinctly but not greatly dilated in male; hind tibia without long
	fine hairs apically on posterior surface houghi Coquillett.
	Costal margin of wing not suffused proximad of a vertical line drawn
	from outer cross-vein10
10.	The spots at apex of second vein and on middle of ultimate section of third
	almost directly above outer cross-vein, sometimes connected with it;
	second segment of hind tarsus of male broader than long; hind tibia of
	male with some long fine hairs on postero-ventral and posterior surfaces
	apicallycompedita Loew.
	The spots above referred to distinctly distad of the one on outer cross-vein
	and not connected with it; second segment of hind tarsus of male distinctly
	longer than wide; hind tibia of male without long fine hairs apically, disjuncta Johnson (similata Malloch).
11	The entire costal margin of wings broadly brown including the costal and
41.	subcostal cellssheldoni Coquillett,
	Costal margin of wing largely hyaline, clouded only from a little before apex
	of second vein12
12.	Thorax with 4 pairs of strong dorsocentral bristles13
	Thorax with 3 pairs of strong dorsocentral bristles14

13.	Arista plumose; the fuscous spot on middle of ultimate section of third vein of wing separated from the one at apex of second and much distad of the outer cross-vein; hypopygium as in Figure 19 philadelphica Macquart. Arista short haired; the spot at middle of ultimate section of third vein connected with the one at apex of second and directly above outer cross-vein; hind femur without preapical anteroventral bristle, conjuncta Johnson.
	Arista short haired; wing markings as in conjucta; hind femur with at
	least one long preapical anteroventral bristle citreifrons Malloch.
14.	Thorax without differentiated acrostichals except the prescutallar pair;
	base of third vein pale; hind femur without an outstanding preapical
	anteroventral bristle; hypopygium as in Figure 22 conjuncta Johnson.
	Thorax with well differentiated acrostical bristles15
15	Hind femur of male without an outstanding bristle near apex on antero-
10.	ventral surface; base of third vein dark brown, much darker than the
	remainder of vein; two pairs of acrostichals proximad of anterior pair
	of dorsocentrals, the anterior pair much weaker than the second,
	fuscibasis Malloch,
	Hind femur with an outstanding bristle near apex on anteroventral surface
	in both sexes; base of third vein not darker than remainder of vein; one
	very strong pair of acrostichals proximad of the anterior pair of dorso-
	centrals proximad of which there are no well-developed bristles,
	incerta Malloch,
16.	Wing with both cross-veins broadly infuscated, the infuscation extending
	well onto the membrane17
	Wing with the cross-veins not noticeably darker than the others; if so, the
	infuscation does not extend onto the membrane 18
17.	Male with anteroventral and anterior surfaces of hind tibia and anterior
	surface of basal segment of hind tarsus with long, soft, erect hairs; the
	last abdominal sternite with an apical series of short black setulae;
	hypopygium as in Figure 23 nubilifera Malloch,
	Male without soft, erect hairs on hind tibia and tarsus; last abdominal
	sternite with a few weak hairs apically nubila Melander.
18.	Males
	Females29
19.	Hind femur with a large number of short setulae on basal half of ventral
	surface; cheek over half as high as eye; hind tibia without erect, soft
	hairs littoralis Malloch.
42.0	Hind femur without black setulae on basal half of ventral surface 20
20.	Hind tibia without erect, soft hairs ventrally 21
0.4	Hind tibia with some soft, erect hairs ventrally 25
21.	Claws of mid tarsus unequal in size, the anterior one distinctly larger than
	the posterior, and peculiarly curved; cheek about half as high as eye;
	hairs on lower half of back of head and on cheek pale harti Malloch,
()()	Claws of mid tarsus equal in length, with the normal curvature 22
4.4.	Hind femur without a preapical bristle on anteroventral surface; sixth
	tergite of abdoment fully twice as long as fifth23 Hind femur with a distinct preapical anteroventral bristle24
99	Hind femur with a distinct preapical anteroventral bristle24 Arista pubescent; hind femur with some fine, short hairs apically on poster-
	oventral surfaceinaequalis Malloch.
	Arista short haired; ventral surfaces of hind femur entirely bare,
	nudifemur Malloch, new species.
	munional mattor, her species.

24. Eighth abdominal tergite without an obtuse angle caudad of the slende downwardly projecting lateral process; hind femur without erect, sof hairs on posteroventral surface————————————————————————————————————	t a. e r
25. Hind femur without a long fine hair close to apex on posteroventral surface last abdominal sternite with two long tapering processes which ar pointed at apicesbispina Loew Hind femur with one or more long fine hairs near apex on posteroventra surface, sometimes the entire surface has a fringe of hairs; apices of	; e v.
processes of last sternite rounded	ճ d 7 d
27. Hind femur with rather dense, long, fine hairs on its entire length posteror ventrally; the small spine at base of the slender inner hypopygial forcep long and simple (fig. 28) imitatrix Malloch Hind femur with sparse fine hairs on posteroventral surface which do not form a complete frings; the small spine at base of the slender inner	s ı. ot
hypopygial forceps short, furcate (fig. 25) fratercula Malloci 28. LIGHT OF SPECIES OF THE DISTRICT OF COLUMNIA RECION	

S. aequalis Malloch.—Dead Run, Virginia, June 22, 1915, R. C. Shannon.

S. bispina Loew.—This species has been collected a number of times by various collectors on Plummer Island, Maryland, from May 30 to August 4; and at Beltsville, Maryland, May 25, 1919, McAtee; Dead Run, Virginia, August 3, 1915, V. A. Roberts; and Chain Bridge, Virginia, August 20, 1922, Malloch.

S. cilifera Malloch.—Plummer Island, Maryland, May 9, 1914.

R. C. Shannon.

- S. citreifrons Malloch.—Beltsville, Maryland, May 21, 1922, Glen Echo, Maryland, June 18, 1922, Malloch.
- S. compedita Loew.—Very common; has been collected on dates ranging from May 11 to October 9; in copula June 23; comes to light and visits the flowers of Castanea pumila and Ceanothus americanus. V. P. I.
- S. conjuncta Johnson.—District of Columbia, D. W. Coquillet; Falls Church, Virginia, June 22, N. Banks; Dead Run, Virginia, June 6, 1914, R. C. Shannon.
- S. disjuncta Johnson.—Frequently taken during a season with May 25 and September 8 at its extremes; there are no records from the upper Potomac Valley where so many of the other species have been collected.
- S. fraterna Loew.—Dead Run, Virginia, June 22, July 28, 1915, R. C. Shannon; Cabin John, Maryland, July 31; August 8, Glen Echo, Maryland, July 17, August 8, 28, 1921, July 9, 16, August 6, 22, 1922, Malloch.
- *S. fuscibasis Malloch.—Dead Run, Virginia, June 22, 1916, June 29, 1915, R. C. Shannon; Falls Church, Virginia, August 7, N. Banks; Plummer Island, Maryland, June 29, September 13, 1914. McAtee; July 31, 1913, R. C. Shannon.
- S. houghi Coquillett.—Has been taken a number of times, but does not appear at all common; season June 4 to August 26: in copula June 4, July 14; visits flowers of Ceanothus americanus and Xolisma liquistrina. V. P. I.
- S. imitatrix Malloch.—Washington, District of Columbia, April 17, 1923, E. N. Cory; Beltsville, Maryland, May 21, 1922, Malloch.
- * S. incerta Malloch.—Common; dates of collection range from June 8 to October 2; comes to light. P. I.
- S. nubila Melander.—Arlington, Virginia, June 6, 1914, R. H. Hutchinson.
- S. nubilifera Malloch.—Plummer Island, Maryland, June 8, 1914, at light, R. C. Shannon; August 27, 1913, H. S. Barber; Cabin John Bridge, Maryland, June 14, 1913, R. C. Shannon.
- S. philadelphica Macquart.—Common; June 9 and September 28 mark the extremes of the season during which it has been collected; comes to light. P. I.

S. seticauda Malloch.—Plummer Island, Maryland, May 30, 1913,

R. C. Shannon; June 2, 1912, July 19, 1914, McAtee.

S. tenuispina Loew.—Great Falls, Virginia, June 21; Falls Church Virginia, June 24, N. Banks: Plummer Island, Maryland, May, 1908, William Palmer; May 23, 1914, June 9, 1913, R. C. Shannon; May 24, 1914, June 29, 1913, McAtee; Glen Echo, Maryland, August 2, 1922, Malloch.

DESCRIPTIONS OF TWO NEW SPECIES.

SAPROMYZOSOMA DECEPTOR Malloch, new species.

Female.—Similar to fraterna in color. Most closely allied to notata Fallen, differing in having the wing markings less distinct, the arista with its longest hairs not noticeably longer than its basal diameter, and the bristles over all not so long and strong.

Length, 3 mm.

Type and one paratype.—White Mountains, New Hampshire (Morrison). Type, Cat. No. 26390. U.S.N.M.

SAPROMYZOSOMA NUDIFEMUR Malloch, new species.

Male.—Agrees with inaequalis and its allies in color, but in the two specimens before me there is a dark part on third vein beyond outer cross-vein at the point where the dark spot is present in those forms that have distinct spots on wings. There are no hairs between the acrostichal bristles but otherwise the thorax is as in inaequalis. The tergites of abdomen descend so far that it is impossible to distinguish the fifth sternite, but it has evidently no long processes.

Length, 3 mm.

Type and one paratype.—Kaslo, British Columbia, June 23 and July 7 (R. P. Currie). Type, Cat. No. 26391. U.S.N.M.

Genus PERISCELIS Loew.

This genus is somewhat doubtfully placed in the Sapromyzidae owing to the lack of mesopleural and preapical tibial bristles as well as the presence of but one orbital bristle. The divergent postvertical bristles and peculiar subcostal vein, which is similar to that of the Trypetidae, distinguish the genus from any other in the three families dealt with in this paper, but it is more evidently related to Sapromyzidae than to any other family.

At present it is recorded only from Illinois, where it has been taken on sap exuding from trees, but its small size and habits probably accounts for its absence from collections. Malloch redescribed this genus under the name *Phorticoides* with one species, *flinti* Malloch, which may be synonymous with annulata Fallen, a European

species.

GENUS TRYPETISOMA Malloch, new genus.

This genus is erected for the reception of Sapromyza stictica Loew. Characters as indicated in generic key on page 17.

Genotype.—Sapromyza stictica Loew.

T. stictica (Loew).—Originally described from District of Columbia material. For specific characters see key to species of Sapromyza, p. 17.

BIBLIOGRAPHY.

COQUILLETT, D. W.

New species of Sapromyzidae.

Can. Ent., vol. 30, no. 11, November, 1898, pp. 277-280.

Describes Sapromyza magna from District of Columbia material, p. 279.

New acalyptrate Diptera from North America.

Journ. N. Y. Ent. Soc., vol. 10, no. 4, December, 1902, pp. 177-191.

Describes Sapromyza glauca from Marlboro, Maryland, p. 177.

LOEW, H.

Diptera Americae septentrionalis indigena. Complete work, 1872.

Describes the following three species from our region:

Sapromyza umbrosa District of Columbia, vol. 1, p. 132.

Sapromyza stictica District of Columbia, vol. 1, p. 133.

Lauxania flaviceps District of Columbia, vol. 2, p. 110.

MALLOCH, J. R.

Some undescribed North American Sapromyzidae.

Proc. Biol. Soc. Wash., vol. 27, pp. 29-42, pl. 2, March 20, 1914.

Records seven species from the vicinity of Washington, District of Columbia, of which six are described as new. One of these Sapromyza similata proved to have been previously described as S. disjuncta Johnson.

Some new North American Sapromyzidae (Diptera).

Can. Ent., vol. 52 ,nos. 6-7, June-July, 1920, pp 126-128.

Sapromyza fuscibasis, new species is described from Plummer Island, Maryland.

Some new genera and species of Lonchaeidae and Sapromyzidae (Diptera.) Proc. Ent. Soc. Wash., vol. 25, no. 2, February, 1923, pp. 45–53. Eight new species from this region are described.

MELANDER, A. L.

A synopsis of the Sapromyzidae.

Psyche, vol. 20, no. 2, April, 1913, pp. 57-82, pl. 3.

Records five species from the District of Columbia.

EXPLANATION OF PLATES.

PLATE 1.

Structural details of Lonchaeidae and Sapromyzidae.

FIGURE 1. Lonchaea polita, hypopygium of male, ventral view, one side.

- 2. Lonchaea winnemana, head, dorsal view.
- 3. Lonchaca nudifemorata, hypopygium of male, ventral view, one side.
- 4. Lonchaea winnemana, wing.
- 5. Minettia americana, hypopygium of male, ventral view, one side.
- 6. Minettia americana, same, dorsal view, one side,

- FIGURE 7. Minettia americana, same, lateral view.
 - 8. Minetta obscura, hypopygium of male, ventral view, one side.
 - 9. Minetta lupulina, hypopygium of male, ventral view, one side.
 - 10. Sapromyza serrata, hypopygium of male, side view.
 - 10a. Sapromyza serrata, inferior forceps.
 - 11. Sapromyza obtusilamellata, hypopygium of male, ventral view.
 - 12. Sapromyza obtusilameellata, same, rear view.
 - 13. Sapromyza annulata, hypopygium of male, rear view.
 - 13a. Sapromyza annulata, inferior forceps.
 - 14. Sapromyza pictiventris, hypopygium of male, rear view.
 - 14a. Sapromyza pictiventris, inferior forceps.
 - 15. Sapromyza quadrilineata, hypopygium of male, rear view
 - 15a. Sapromyza quadrilineata, inferior forceps.

PLATE 2.

Hypopygia of Sapromyzidae.

- FIGURE 16. Camptoprosopella rerticalis, genitalia of female, ventral view, one side.
 - 17. Camptoprosopella verticalis, hypopygium of male, side view.
 - 18. Sapromyzosoma fraterna, hypopygium of male, side view.
 - 19. Sapromyzosoma philadelphica, hypopygium of male, side view.
 - 20, Sapromyzosoma fraterna, inferior forceps of male.
 - 21. Sapromyzosoma fraterna, hypopygium of male, ventral view, one side.
 - 22. Sapromyzosoma conjuncta, hypopygium of male, side view.
 - 23. Sapromyzosoma nubilifera, hypopygium of male, side view.
 - 24. Sapromyzosoma pernotata, inferior forceps.
 - 25. Sapromuzosoma fratercula, hypopygium of male, side view.
 - 26. Sapromyzosoma pernotata, hypopygium of male, side view.
 - 27. Sapromyzosoma tenuispina, superior forceps.
 - 28. Sapromyzosoma imitatrix, hypopygium of male, side view.

ADDENDUM.

After the manuscript of this paper was sent to the press a paper by Dr. A. H. Sturtevant appeared in which he records *Periscelis annulata* Fallen from Alabama, South Dakota, and New Mexico.⁶

In the same paper he describes a new genus and species, Sphyro-periscelis wheeleri Sturtevant, from Massachusetts. This genus differs from Periscelis in having the frons much wider, about three times as wide as either eye, the antennal bases separated by about as great a distance as either is from eye, not rather closely approximated, the front of frons flattened, and the outer cross-vein of wing lacking. We have not seen the genus.

⁶ Amer. Mus. Novit., No. 76, p. 1, May 21, 1923.
